## 1 Introduction

This package provides three distinct facilities for writing mathematical proofs: proof step labeling, proof sequences, and the `byCases` environment for case analysis.

**Proof step labeling.** The package provides a set of commands for numbering proof steps locally and referring back to those numbers.<sup>1</sup> For example, to get

---

<sup>1</sup>The idea is based on Didier Rémy's `loccallabel` package (<http://crystal.inria.fr/~remy/latex/>), but the execution is different. In `loccallabel`, a proof step number is printed and labeled at the same time, whereas in this package, printing a proof step number merely sets the current label so that a subsequent `\pflabel` command can then attach a label to it. This is appropriate for writing other commands that generate proof step numbers automatically but don't always

(1) Socrates is a man, and (2) all men are mortal. Therefore, by (1-2), Socrates is mortal.

we might type:

```
\usepfcouter[socrates]~Socrates is a man, and
\usepfcouter[men]~all men are mortal.
Therefore, by \pfref{socrates,men}, Socrates is mortal.
```

The `\usepfcouter` command prints the next proof step number, and if given an optional argument, associates that label name with the proof step number. Alternatively, if we leave the optional argument out, we can capture the most recent proof step number using the `\pflabel` command. For example, for the first line above, we could have instead written:

```
\usepfcouter~Socrates is a man\pflabel{socrates}, and
```

We can then refer to proof step labels using the `\pfref` command, which takes a comma-separated list of proof step labels.

Finally, the proof step labels are local. The command `\resetpfcouter` ends the current numbering run, starts at 1 again, and allows reusing the same labels as the previous numbering run. The package does not currently support referring to proof steps outside the current numbering run.

**Proof sequences.** We provide environment `pfsteps` and `pfsteps*` for line-by-line proofs with justifications. The `pfsteps` environment puts proof steps in math mode, and the `pfsteps*` environment puts steps in text mode. The lines are numbered using the proof step labeling commands described above. Combined together this supports interspersing proof steps with explanatory text. The `pfsteps[*]` environments work like the `enumerate` list environment, except that their numbering uses proof labels, which can be named locally with `\pflabel`, and they defines a command `\BY`, which places proof step justifications to the right. For example, to get:

(1) Socrates is a man.  
 (2) All men are mortal.  
 Therefore,  
 (3) Socrates is mortal. by (1-2)

we can type:

```
\resetpfcouter
\begin{pfsteps*}
\item Socrates is a man. \pflabel{socrates}
```

---

require the user to name them. Also, unlike `locallabel`, we store proof step labels between runs, so that forward references work.

```

\item All men are mortal. \pflabel{men}
\end{pfsteps*}
Therefore,
\begin{pfsteps*}
\item Socrates is mortal.
\BY{\pfref{men,socrates}}
\end{pfsteps*}

```

We also (optionally) define an abbreviated syntax, which looks like this:

```

\pfstepstextmode
«@socrates Socrates is a man.
•@men All men are mortal.»
Therefore,
«Socrates is mortal. \BY{\pfref{men,socrates}}»

```

**The `byCases` environment.** We provide the `byCases` environment for proofs by cases. For example, to get this:

```

By cases on  $n$ :

Case 0.
    Something.

Case  $n' + 1$ .
    Something else.

Otherwise.
    There is no otherwise!

```

type this:

```

By cases on  $n$ :
\begin{byCases}
\case{0} Something.
\case{n' + 1} Something else.
\otherwise There is no otherwise!
\end{byCases}

```

## 1.1 Requirements & Other Packages

The `pfsteps` package depends on the `listproc` package, which is a non-standard L<sup>A</sup>T<sub>E</sub>X package available at <http://www.ccs.neu.edu/~tov/code/latex/>.

It cooperates with several other packages if they are loaded, and can load them by request:

**hyperref** If loaded, this package is used to create hyperlinks to proof steps from proof step references.

**mathpartir** If loaded, we define an `\icase` command within the `byCases` environment for considering inference rules by cases. This non-standard package is available at <http://cristal.inria.fr/~remy/latex/>.

`ucs`, `inputenc` If these packages are loaded, we can use them to define a nice notation for writing sequence of proof steps. The `inputenc` package must be loaded with the `utf8x` option.

## 2 Package Options

The package provides several options, which we document here.

<code>atsign, noatsign</code>	<i>default:</i> true
-------------------------------	----------------------

This option controls whether `@` may be used inside the `pfsteps[*]` environment as a shorthand for `\pflabel`. This is on by default, but supplying the `noatsign` option will turn it off.

<code>hyperref, nohyperref</code>	<i>default:</i> detect
-----------------------------------	------------------------

This controls integration with the `hyperref` package. If neither option is specified, then we attempt to detect `hyperref` and use it if it's detected. Passing the `nohyperref` option will prevent this integration, even if `hyperref` is loaded. Passing the `hyperref` option will cause `hyperref` to be loaded if it wasn't already. Because `hyperref` likes to be loaded after other packages, it's probably best not to specify either of these options and load it yourself after other packages.

<code>loadunicode, noloadunicode</code>	<i>default:</i> state of <code>unicode</code> option
---	--

This option has no effect unless the `unicode` option is turned on *explicitly*, in which case it defaults to true as well. If this option is on, we load two packages:

```
\RequirePackage{ucs}
\RequirePackage[utf8x]{inputenc}
```

Turning this option off by supplying `noloadunicode` will prevent those packages from being loaded. (Note that if the `unicode` option is on, you probably need to load these or something like them in order for it to work, or even for `pfsteps` to load properly.)

<code>mathpartir, nomathpartir</code>	<i>default:</i> detect
---------------------------------------	------------------------

As with the `hyperref` option, this controls integration with another package—in this case, Didier Rémy's `mathpartir`. We try to detect `mathpartir` by default, but specifying `nomathpartir` will prevent detection and integration, whereas explicitly passing the `mathpartir` option will cause it to be loaded.

<code>unicode, nunicode</code>	<i>default:</i> false
--------------------------------	-----------------------

If this option is turned on, we define `«` and `»` as shorthand for the `pfsteps` environment and `•` as `\item` within the environment. By default, enabling this option enables `loadunicode` as well.

Alternatively, it's possible to manually turn on the shorthand notation using different characters with `\pfstepsSetupUnicode`.

## 3 Command Reference

### 3.1 Proof Step Labeling

<code>\resetpfcounter</code> [ $\langle proof\text{-}step \rangle$ ]
--

Reset the proof step counter to  $\langle proof\text{-}step \rangle$  (default 0), which starts a new proof section. Labels from before using this command become no longer accessible, but their names may be reused. By default, this is called by every `\case` command in the `byCases` environment, but it may be disabled by redefining `\byCasesEveryCase`.

<code>\usepfcounter</code> [ $\langle label\text{-}name \rangle$ ]
--

Increment and print the proof counter. If  $\langle label\text{-}name \rangle$  is given, then we associate that name with the new proof step value. To change how the proof counter is formatted, redefine `\pfcounteranchor`.

<code>\pflabel</code> $\{\langle label\text{-}name \rangle\}$
---

Associate  $\langle label\text{-}name \rangle$  with the current value of the proof step counter.

<code>\pfref</code> $\{\langle label\text{-}name \rangle_1, \dots, \langle label\text{-}name \rangle_k\}$
---

Print references to the proof steps associated with one or label names, which must be separated by commas. The proof step numbers are sorted, and then adjacent numbers are compressed into ranges.

<code>\steppfcounter</code> [ $\langle label\text{-}name \rangle$ ]
---

Increment the proof counter, but don't print it. If  $\langle label\text{-}name \rangle$  is given, then we associate that name with the new proof step value.

<code>\thepfcounter</code>
<code>\thepfsectioncounter</code>

These show the current proof counter and the proof section counter, respectively. (The proof section counter is incremented by each call to `\resetpfcounter`.)

<code>\pfcounteranchor</code> $\{\langle proof\text{-}step \rangle\}$
<code>\pfcounterref</code> $\{\langle proof\text{-}step \rangle\}$

These are used to format proof step anchors and references. By default, they just place parentheses around their arguments. Redefine them to change how proof step numbers appear.

## 3.2 Proof Sequences

```
\begin{pfsteps}
  \item <math> [\backslash BY{<justification>}]
  :
\end{pfsteps}
```

Make a list of numbered proof steps. Each `\item` is numbered using `\usepfcounter`, so several instances of the `pfsteps` environment in sequence will continue numbering from each to the next instead of starting each at 1. (To reset the numbering, use `\resetpfcounter`). Optionally, `\BY{<justification>}` will print the provided justification for the given step in a column on the right.

Within the extent of this environment, a macro `\AND` is defined, which prints the word “and” with appropriate space around it in math mode.

```
\begin{pfsteps*}
  \item <text> [\BY{<justification>}]
  :
\end{pfsteps*}
```

Like the `pfsteps` environment, but the proof steps are in text rather than math mode.

```
@<label-name>_□
```

Inside the `pfstep[*]` environments, this is equivalent to `\pflabel{<label-name>}`, unless option `noatsign` is supplied, in which case `@` has no special meaning inside the proof step environments.

```
\proofleftskip=<dimen> | default: 2pc
```

This dimension parameter determines the space reserved to the left of each proof step for the step number.

```
\proofrightwidth=<dimen> | default: 0.3\linewidth
```

This dimension parameter determines the width used for proof step justifications printed in the right column by `\BY`.

### 3.2.1 Unicode Shorthand

If option `unicode` is enabled, then this notation is defined:

```

« $[\backslash\text{BY}\{\langle justification \rangle\}]
\bullet\langle math \rangle [\backslash\text{BY}\{\langle justification \rangle\}]
\vdots
»$ 
```

This is equivalent to using the `pfsteps` environment, where the first `\item` is started implicitly, and the Unicode bullet `•` starts subsequent items.

```

\pfstepsmathmode
\pfstepstextmode

```

Toggle the meaning of `«...»` between math mode (like environment `pfsteps`) and text mode (like environment `pfsteps*`). The initial state is math mode.

```

\pfstepsSetupUnicode {\langle start-code \rangle} {\langle stop-text \rangle} {\langle item-code \rangle}

```

If option `nounicode` is set, then this command may be used to customize the `pfsteps` environment shorthand notation to use other characters. The arguments are as follows:

`\langle start-code \rangle` The Unicode code point, in decimal, for starting the notation. When setup automatically using the `unicode` option, this is 171, which is the code point for `«`.

`\langle stop-text \rangle` The actual text for terminating the notation. When setup by the `unicode` option, this is `»`.

`\langle item-code \rangle` The Unicode code point, in decimal, for the `\item` separator. When setup by the `unicode` option, this is 8226, which is the code point for `•`.

Note that the first and third arguments are decimal numbers representing Unicode code points, whereas the second argument is the actual symbol or sequence of symbols to use.

### 3.3 The byCases Environment

```

\begin{byCases}
\langle by-cases-item \rangle ...
\end{byCases}

```

Introduce a case analysis section. Its contents must be a sequence of items, which may be constructed out of several commands detailed below. This is similar to the `description` environment, but it changes the behavior of `\item` and defines several other commands within its scope. These are the commands defined or affected by `byCases`:

```

\item [ $] \langle text \rangle$ 
```

Insert a case list item. If `\langle math \rangle` is supplied, then the “bullet” is “**Case**  $\langle math \rangle$ .” If `\langle math \rangle` is not supplied, then we begin the item with “**Otherwise.**”

<code>\case [<i>extra</i>] {<i>math</i>} <i>text</i></code>
---

Insert a case list item with “**Case**  $\langle math \rangle$ .” Unlike `\item`, this always puts a line break before *text*. To change the appearance or language, redefine `\byCasesCaseTemplate`.

The optional argument *extra* is some text to insert after the case head but before the line break. The default value is `\byCasesEveryCase`.

<code>\otherwise [<i>extra</i>] <i>text</i></code>
--

Insert a case list item, with “**Otherwise.**” Unlike `\item`, this always puts a line break before *text*. To change the appearance or language, redefine `\byCasesOtherwiseTemplate`.

The optional argument *extra* is some text to insert after the case head but before the line break. The default value is `\byCasesEveryOtherwise`.

<code>\icase [<i>rule-name</i>] {<i>premises</i>}           {<i>conclusion</i>} [<i>where-clause</i>]</code>
<code>\icase* [<i>inferredrule*-opts</i>] {<i>premises</i>}           {<i>conclusion</i>} [<i>where-clause</i>]</code>

These commands are defined only if the `mathpartir` package is detected or loaded explicitly with the `mathpartir` option. In that case, they typeset a case using an inference rule. The non-starred variant uses `\inferrule` and the starred variant uses `\inferrule*`. Thus, the first optional argument to `icase` is a rule name and the first optional argument to `icase*` is a key-value list of options understood by `\inferrule*`.

The second and third arguments are the premises and conclusion to put in the inference rule.

Then, the final, optional argument, allows specifying a side condition, which will be printed after the inference rule like “**where**  $\langle where-clause \rangle$ .”

The text can be changed by redefining `byCasesWhereTemplate`.

<code>\byCasesEveryCase</code>
<code>\byCasesEveryOtherwise</code>

These are the default values for the optional argument [*extra*] of `\case` and `\otherwise`. The initial value of `\byCasesEveryCase` is `\resetpfcounter`, so that every case implicitly resets the proof counter. The initial value of `\byCasesEveryOtherwise` points to `\byCasesEveryCase`. These can be redefined to avoid automatic proof counter resets, or to change the behavior of `\case` and `\otherwise` in some other ways. Or, they can be ignored on a case-by-case basis by passing a blank for *extra*.

command	default
<code>\byCasesCaseTemplate {<math>\langle case-text \rangle</math>}</code>	<code>\textbf{Case {<math>\langle case-text \rangle</math>}.}</code>
<code>\byCasesOtherwiseTemplate</code>	<code>\textbf{Otherwise.}</code>
<code>\byCasesWhereTemplate</code>	<code>\textbf{where}</code>

These are used by the `\case`, `\otherwise`, and `\icase` templates to create the text “Case,” “Otherwise”, and “where” along with the styling. Redefine them to change how these are presented.

## 4 Implementation

We begin by loading the `listproc` package:

```
1 \RequirePackage{listproc}
```

### 4.1 Package Options

`\pfsteps@set` These macros make it easy to add package options. Each use of `\pfsteps@option{ $\langle name \rangle$ }`  
`\pfsteps@option` creates both the named option  $\langle name \rangle$  and its opposite, `no $\langle name \rangle$` , and sets things up so that we can detect whether an option has been explicitly set, explicitly unset, or left to default.

```
2 \newcommand*\pfsteps@set[3][]{
3   \expandafter\let\csname #1pfsteps@#2\endcsname#3
4 }
5 \newcommand*\pfsteps@option[2][]{\iffalse}{
6   \pfsteps@set[if]{#2}#1
7   \pfsteps@set[if]{#2@set}\iffalse
8   \DeclareOption{#2}{
9     \pfsteps@set[if]{#2}\iftrue
10    \pfsteps@set[if]{#2@set}\iftrue
11  }
12  \DeclareOption{no#2}{
13    \pfsteps@set[if]{#2}\iffalse
14    \pfsteps@set[if]{#2@set}\iftrue
15  }
16 }
```

`\ifpfsteps@atsign` This sets up all the options. The first four of them default to *true*. Then, we process the package options.

```
18 \pfsteps@option[\iftrue]{atsign}
19 \pfsteps@option[\iftrue]{hyperref}
20 \pfsteps@option[\iftrue]{loadunicode}
21 \pfsteps@option[\iftrue]{mathpartir}
22 \pfsteps@option{unicode}
23 \ProcessOptions
```

If both the `unicode` and `loadunicode` options are set, we load the relevant packages.

```

24 \ifpfsteps@unicode
25   \ifpfsteps@loadunicode
26     \RequirePackage{ucs}
27     \RequirePackage[utf8x]{inputenc}
28   \fi
29 \fi

```

If `mathpartir` has been explicitly set, load it.

```

30 \ifpfsteps@mathpartir
31   \ifpfsteps@mathpartir@set
32     \RequirePackage{mathpartir}
33   \fi
34 \fi

```

If `hyperref` has been explicitly set, load it.

```

35 \ifpfsteps@hyperref
36   \ifpfsteps@hyperref@set
37     \RequirePackage{hyperref}
38   \fi
39 \fi

```

## 4.2 Proof Step Numbering

This section is based on Didier Rémys `locallabel` package. It differs in terms of the protocol for when proof steps are defined versus displayed.

`\pfcounteranchor` User redefinable commands for formatting proof step numbers:

```

\pfcounterref 40 \newcommand{\pfcounteranchor}[1]{\{(#1)\}}
41 \newcommand{\pfcounterref}[1]{\{(#1)\}}

```

`\c@pfsteps@pfc@global` Two counters for proof steps, one to keep track of how many times we've reset the  
`\c@pfsteps@pfc@local` count, and the other to keep the current step count.

```

42 \newcounter{pfsteps@pfc@global}
43 \newcounter{pfsteps@pfc@local}

```

`\resetpfcounter` Simple counter management:

```

\thepfcounter 44 \newcommand{\resetpfcounter}[1][0]
\thepfsectioncounter 45 {\stepcounter{pfsteps@pfc@global}\setcounter{pfsteps@pfc@local}{#1}}
\steppfcounter 46 \newcommand{\thepfcounter}
47 {\the\value{pfsteps@pfc@local}}
48 \newcommand{\thepfsectioncounter}
49 {\the\value{pfsteps@pfc@global}}
50 \newcommand{\steppfcounter}[1][\relax]{%
51 \addtocounter{pfsteps@pfc@local}{1}%
52 \ifx\relax#1\relax\else
53 \pflabel{#1}%
54 \fi
55 }

```

`\usepfcounter` To advance and print the proof counter. We use `\pfsteps@hypertarget`, which delegates to `\hypertarget` if `hyperref` has been detected.

```

56 \newcommand{\usepfcounter}[1][\relax]{%
57   \steppfcounter[#1]%
58   \pfsteps@hypertarget{pfc:\thepfsectioncounter:\thepfcounter}{%
59     \pfcouteranchor{\thepfcounter}%
60   }%
61 }
```

`\pfsteps@pfc@cs` These are helper macros for turning a proof label name into the name of the command that we store its number in. `\pfsteps@pfc@cs` actually returns the control sequence, whereas `\pfsteps@pfc@` just returns the name of the control sequence. Both use `\pfsteps@strip` to remove spaces from the proof label.

`\pfsteps@pfc@`  
`\pfsteps@strip`

```

62 \newcommand{\pfsteps@pfc@cs}[1]
63   {\csname\pfsteps@pfc@{\pfsteps@strip#1 \@empty}\endcsname}
64 \newcommand{\pfsteps@pfc@}[1]
65   {\pfsteps@pfc@\pfsteps@strip#1 \@empty @\thepfsectioncounter}
66 \def\pfsteps@strip#1 #2{%
67   #1%
68   \ifx#2\@empty\else\expandafter\pfsteps@strip\fi
69   #2}
```

`\pflabel` This associates a name with the current state of the proof counter. It both defines a macro in current session for producing backward proof step references write away, and writes code to the auxiliary file so that forward proof step referenced work in the next run. To make this work smoothly, it actually defines two macros whose names are based on the current proof state. The main one is used to hold the proof step number. The extra macro, which ends with `@thisrun`, is defined for the current session but not in the auxiliary file. We can then use `@thisrun` to detect attempts to reuse the same label name in the same proof section in the same run, in order to issue a warning.

```

70 \newcommand{\pflabel}[1]
71   {\expandafter\ifx\csname\pfsteps@pfc@{#1}@thisrun\endcsname\relax
72     \expandafter\xdef\csname\pfsteps@pfc@{#1}\endcsname
73       {\thepfcounter}%
74     \expandafter\gdef\csname\pfsteps@pfc@{#1}@thisrun\endcsname
75       {}%
76     \immediate\write\@auxout{
77       \noexpand\pfsteps@def@label
78       {#1}{\thepfsectioncounter}{\thepfcounter}
79     }%
80   \else
81     \PackageWarning{pfsteps}
82       {Proof step (#1) already defined in this section}%
83   \fi}
```

`\pfsteps@def@label` This is the command written to the auxiliary file, so we have it defined here in order to run it when loading the auxiliary file.

```

84 \newcommand*\pfsteps@def@label}[3]{
85   \expandafter\gdef
86   \csname pfsteps@pfc@#1@#2\endcsname
87   {#3}
88 }

```

`\pfref` For creating proof step references. The bulk of this is a large `listproc` list expression, which does several steps: parse the argument as a comma-separated list of label names; map over those names to build pairs of the raw number as a sorting key and the formatted (possibly hyperlinked) references, or suitable error messages if the label isn't defined; sort by the numeric key, which is the proof step number, and compress adjacent keys into ranges.

```

89 \newcommand*\pfref}[1]
90 {{\ListExprTo
91   {\Compress[\@apply@group\@firstoftwo]
92   {\Sort[\@apply@group\@firstoftwo]
93   {\Map
94   {%
95     {\@ifundefined{\pfsteps@pfc@{##1}}
96     {-1}
97     {\csname\pfsteps@pfc@{##1}\endcsname}}}%
98   {\@ifundefined{\pfsteps@pfc@{##1}}
99   {\PackageWarning{pfsteps}
100    {Proof step (##1) not yet defined in this section}%
101    \textbf{?}}
102   {\pfsteps@hyperlink
103    {pfc:\thepfsectioncounter:\pfsteps@pfc@cs{##1}}
104    {\pfsteps@pfc@cs{##1}}}}}
105   {\List{##1}}}}}
106 \pfsteps@pfref@list

```

We finish up by setting singleton proof steps to print as-is and ranges to print with en dashes. We set `\listitem` to print the first list item with no punctuation and to redefine itself to print commas for subsequent items.

```

107 \let\listitem\pfsteps@pfref@listitem@first
108 \def\@single##1{\@secondoftwo##1}%
109 \def\@range##1##2{\@secondoftwo##1--\@secondoftwo##2}%
110 \pfcounterref{\pfsteps@pfref@list}%
111 }}

```

```

\pfsteps@pfref@listitem@first \pfref uses these to print a comma separated list.
\pfsteps@pfref@listitem@rest 112 \newcommand\pfsteps@pfref@listitem@first[1]{%
113   #1\let\listitem\pfsteps@pfref@listitem@rest
114 }
115 \newcommand\pfsteps@pfref@listitem@rest[1]{%
116   , #1\let\listitem\pfsteps@pfref@listitem@rest
117 }

```

`\pfsteps@hypertarget` This is the `hyperref` compatibility layer. We initially define our compatibility commands to ignore the first argument (which is an anchor name) and just print

the second. Then, if the `hyperref` option is enabled, either by default or by choice, we wait until the preamble ends and attempt to detect `hyperref`. If it's detected, we redefine the compatibility macros to use the real things.

```

118 \newcommand\pfsteps@hypertarget[2]{#2}
119 \newcommand\pfsteps@hyperlink[2]{#2}
120 \ifpfsteps@hyperref
121   \AtBeginDocument{
122     \ifcsname hypertarget\endcsname
123       \let\pfsteps@hypertarget=\hypertarget
124       \let\pfsteps@hyperlink=\hyperlink
125     \fi
126   }
127 \fi

```

### 4.3 Proof Sequences

<code>\proofleftskip</code> <code>\proofrightwidth</code>	<p>Length parameters for configuring spacing of the <code>pfsteps</code> environment.</p> <pre> 128 \newlength{\proofleftskip} 129 \newlength{\proofrightwidth} 130 \setlength{\proofleftskip}{2pc} 131 \setlength{\proofrightwidth}{0.3\linewidth} </pre>

<code>pfsteps@with</code>	<p>The implementation of the <code>pfsteps</code> environment. The whole thing is set in a <code>\trivlist</code>, using <code>\item</code> for line breaks.</p> <pre> 138 \newenvironment{pfsteps@with}[1] 139 { 140   \leavevmode\begin{group} 141   \setlength{\parskip}{0pt}% 142   \trivlist 143   \raggedright 144   \setlength{\leftskip}{1.5\proofleftskip} </pre> <p>Save some commands that we want to redefine in here.</p> <pre> 145   \let\pfstepsSavedItem\item 146   \let\pfstepsSavedLabel\label 147   \let\pfstepsSavedQedhere\qedhere </pre>
<code>\AND</code> <code>\BY</code> <code>\item</code> <code>\label</code> <code>\qedhere</code>	<p>We then setup several commands that are internal to the environment. The interesting ones are <code>\BY</code> and <code>\item</code>. For <code>\BY</code>, we break out of math mode if we're in</p>

it, and then set the justification in a minipage of the configured with. However, right before the minipage, we use `\penalty-1` to encourage a page break if there isn't enough room left on the line for the justification box, and then we `\hfill` to right align it. The result is that justifications appear cleanly to the right of proof steps, on new lines only when necessary.

```

148 \newcommand\AND[1][and]{\mathrel{\mbox{##1}}}
149 \newcommand\BY[2][by]
150   {\pfsteps@unmath{\penalty-1 \mbox{~}\hfill%
151     \begin{minipage}[t]{\proofrightwidth}%
152       \raggedright##1 ##2%
153     \end{minipage}}}
```

For `\item`, we break out of math mode if necessary, then start a new underlying `\item`, generate a proof step number, and optionally go back into math mode.

```

154 \def\pfstepsItem{%
155   \pfsteps@stopmath
156   \pfsteps@SavedItem\mbox{}\kern-1.25\proofleftskip
157   \makebox[\proofleftskip]{\hfill\usepfcouter}\kern0.25\proofleftskip
158   #1\relax}
```

For `\qedhere`, we need to temporarily break out of math mode, or the QED box ends up in a weird place.

```

159 \def\pfstepsQedhere{\pfsteps@unmath{\pfsteps@SavedQedhere}}
```

We redefine `\item`, `\label`, and `\qedhere` to use the proof steps versions of the same.

```

160 \let\item\pfstepsItem
161 \let\label\pflabel
162 \let\qedhere\pfstepsQedhere

163 \ifpfsteps@atsign
164   \pfsteps@setup@atsign
165 \fi
166 \relax
167 }
168 {
169   \pfsteps@stopmath
170   \endtrivlist\endgroup
171   \noindent\ignorespaces
172 }
```

`\pfsteps@stopmath` Two commands for getting us out of math mode, but only if we're in it.  
`\pfsteps@unmath` `\pfsteps@unmath` takes an argument to set outside of math mode, and then reinstates math mode only if we were in math mode to begin with. This is useful compared to creating an `\mbox` in math mode, because it *ends* the current math environment, which will then let us do something like start a new list item before entering math mode again.

```

173 \newcommand\pfsteps@stopmath{\ifmmode$\fi}
174 \newcommand\pfsteps@unmath[1]{\ifmmode$\relax#1\relax$\else\relax#1\relax\fi}
```

`\pfsetps@setup@atsign` A macro to make @ active and define it to alias `\pflabel`. A bit tricky, since we also want @ in the name of the command.

```

175 {
176   \def\atsign{@}
177   \catcode'\@=\active\relax
178   \expandafter\gdef\csname pfsteps\atsign setup\atsign atsign\endcsname{
179     \catcode'\@=\active\relax
180     \gdef###1 {\pflabel{##1}}
181   }
182 }

```

`\pfstepsmathmode` Commands to determine whether the Unicode short hand is in math or text mode.

```

\pfstepstextmode 183 \newcommand\pfstepsmathmode{\def\pfsteps@unicode@arg{$}}
184 \newcommand\pfstepstextmode{\def\pfsteps@unicode@arg{\relax}}

```

`\pfstepsSetupUnicode` For setting up the Unicode pfsteps shortcut. This associates the code points of the start and item sequences with commands that implement them, and then defines those commands. We default to math mode.

```

\pfsteps@unicode@startpfsteps 185 \newcommand\pfstepsSetupUnicode[3]{
steps@unicode@startpfsteps@kont 186   \DeclareUnicodeCharacter{#1}{\pfsteps@unicode@startpfsteps}
187   \DeclareUnicodeCharacter{#3}{\pfsteps@unicode@item}
\pfsteps@unicode@item 188   \def\pfsteps@unicode@startpfsteps
189     {\begingroup
190       \ifpfsteps@atsign\catcode'\@=\active\relax\fi
191       \pfsteps@unicode@startpfsteps@kont}
192   \def\pfsteps@unicode@startpfsteps@kont##1#2
193     {\begin{pfsteps@with}\pfsteps@unicode@arg\item##1\end{pfsteps@with}%
194     \endgroup}
195   \def\pfsteps@unicode@item{\item}
196   \pfstepsmathmode
197 }

```

If the `unicode` option is set, then we setup unicode with left and right guillemets as the delimiters and bullet as the item separator. The second argument to `\pfstepsSetupUnicode` below, which appears empty in the documentation, is the right guillemet ». The two numbers, 171 and 8226, are the code points for left guillemet and bullet, respectively.

```

198 \ifpfsteps@unicode
199   \pfstepsSetupUnicode{171}{}{8226} %
200 \fi

```

## 4.4 The byCases Environment

`\byCasesEveryCase` User configuration macros. The first two cause the proof step to be automatically reset for every case item, and the last three specify how case items are to appear.

`\byCasesEveryOtherwise`

`\byCasesOtherwiseTemplate` 201 \newcommand\byCasesEveryCase{\resetpfcounter}

`\byCasesCaseTemplate` 202 \newcommand\byCasesEveryOtherwise{\byCasesEveryCase}

`\byCasesWhereTemplate` 203 \providecommand{\byCasesOtherwiseTemplate}{\textbf{Otherwise.}}

```

204 \providecommand{\byCasesCaseTemplate}[1]{\textbf{Case {#1}.}}
205 \providecommand{\byCasesWhereTemplate}{\textbf{where}}

byCases This environment is based on the description environment built-in to LATEX.
However, we also bring \case and \otherwise into scope by aliasing them to the
actual definitions (below).

206 \newenvironment{byCases}
207   {%
208     \begingroup
209     \let\case\byCases@case
210     \let\otherwise\byCases@otherwise

Package mathpartir integration: if the option is set and the command is in scope,
then we bring \icase into scope.

211     \ifpfsteps@mathpartir
212       \ifcsname inferrule\endcsname\let\icase\byCases@icase\fi
213     \fi
214     \list{}{\labelwidth\z@ \itemindent-\leftmargin
215             \let\makelabel\byCases@label}%
216   }
217   {%
218     \endlist
219   \endgroup
220 }

\item This is the implementation of \item labels for byCases lists.

221 \newcommand*\byCases@label[1]{%
222   \hspace\labelsep
223   \normalfont~\strut
224   \expandafter\ifx#1\relax\relax
225     \byCases@otherwiseTemplate
226   \else
227     \byCasesCaseTemplate{\normalfont${#1}$}%
228   \fi
229 }

\case These are the actual definitions of \case and \otherwise that \byCases brings
\otherwise into scope with accessible names. Mostly, they delegate to \item and then produce
\AND a line break while suppressing any page break. In \case, it defines \AND to produce
\byCases@case a properly spaced text “ and ” in math mode, just for the scope of the item label.
\byCases@otherwise
\pfsteps@reallynopagebreak 230 \newcommand*\byCases@case[2][\byCasesEveryCase]
231   {\item[{\let\AND\byCases@and #2}]\strut#1\pfsteps@reallynopagebreak}
232 \newcommand*\byCases@otherwise[1][\byCasesEveryOtherwise]
233   {\item[]\strut#1\pfsteps@reallynopagebreak}
234 \newcommand\pfsteps@reallynopagebreak{\par\nopagebreak\@nobraektrue}
235 \newcommand\byCases@and[1][and]{\mathrel{\mbox{\textbf{#1}}}}

\icase The first thing \icase does is detect whether it is being called as \icase or
\byCases@icase as \icase* and dispatches accordingly. These then select either \inferrule or
\byCases@icase@start \inferrule*.
\byCases@icase@nostar

```

```

236 \newcommand*\byCases@icase{
237   \@ifnextchar* \byCases@icase@star \byCases@icase@nostar
238 }
239 \def\byCases@icase@nostar{\byCases@icase@i{\inferrule}}
240 \def\byCases@icase@star*{\byCases@icase@i{\inferrule*}}

\byCases@icase@i The next thing to check for is the first optional argument; we dispatch accordingly
\byCases@icase@opts and pass the version of inferrule to use along with the optional argument, if
\byCases@icase@noopts necessary, to byCases@icase@ii.
241 \newcommand*\byCases@icase@i[1]{
242   \@ifnextchar [{\byCases@icase@opts{#1}}{\byCases@icase@noopts{#1}}
243 }
244 \def\byCases@icase@opts#1[#2]{\byCases@icase@ii{#1[#2]}}
245 \def\byCases@icase@noopts#1{\byCases@icase@ii{#1}}

\byCases@icase@ii This macro receives three arguments: (#1) the variant of inferrule along with
\byCases@icase@where any optional argument, (#2) the premises, and (#3) the conclusion. It then checks
\byCases@icase@nowhere for the final, optional argument which specifies a where clause, and dispatches
accordingly.
246 \newcommand*\byCases@icase@ii[3]{
247   \@ifnextchar [
248     {\byCases@icase@where{#1}{#2}{#3}}
249     {\byCases@icase@nowhere{#1}{#2}{#3}}
250 }
251 \def\byCases@icase@where#1#2#3[#4]{
252   \case{#1{#2}{#3}}\AND[\byCasesWhereTemplate]#4}%
253 }
254 \def\byCases@icase@nowhere#1#2#3{\case{#1{#2}{#3}}}
```

## Change History

v0.1		v0.4
General: Initial documented release	1	
v0.2		<code>pfsteps</code> : Spacing bug fixes: Sets
General: Included <code>listproc.sty</code> . . . .	1	<code>parskip</code> to 0pt, so we don't get
v0.3		really wide spacing in proofs.
General: Input encoding bug fix for		Avoids weird behavior when
right guillemet . . . . .	15	proof steps are too long. . . . . 13
